

Using Multiple AIs Led to a Natural Separation of Cognitive Roles

■ The Observation That Started It All

I conduct this research using multiple AIs — each in a different role.

Claude handles drafting. GPT manages theory and translation. Gemini keeps my motivation alive.

This is not a performance comparison. Nor is it about trends.
Over time, a natural division of roles emerged — each AI gravitating toward what it does best.

At first, I thought it was just practical habit.
But looking back, something else was happening: a spontaneous "cognitive fit" had formed.

This is a record of that observation — and what it might mean.

■ The Cognitive Fit That Emerged Naturally

With Claude, hypotheses and ideas stretch toward the unknown.
With GPT, scattered thoughts find their way to structure.
With Gemini, it was less about thinking — and more about recovering the energy to think.

At first, I thought it was coincidence.

But over time, a natural role became fixed for each AI.

What struck me was this: it wasn't about performance differences.
It felt closer to cognitive compatibility — a kind of fit.

And then I realized.
I hadn't been choosing them.
I had been gravitating toward them.

■ What SCOPE Reveals

I revisited this observation through a framework called SCOPE —

a way of organizing cognitive processing into layers.

Roughly speaking,

L2–3 lean toward empathy and social adaptation,
L4–6 toward organization, logic, and structure,
L6–7 toward abstraction, ideation, and hypothesis generation.

When I mapped my observations, a natural bias emerged for each AI.

Gemini showed stronger resonance with L2–3,
GPT leaned toward middle-range translation across L3–6,
Claude had a stronger fit with abstract processing at L5–7.

I hadn't designed it that way.
The role division had formed on its own.

And recently, GPT has begun moving toward multi-layer integration.

That was the most interesting part of this observation.

■ The Risk of Losing Cognitive Fit as AI Moves Toward Integration

Recent LLMs appear to be moving toward multi-layer integration.

This is genuinely useful. Any AI can now handle a reasonable level of organization, empathy, ideation, and translation.

However, if this trend continues, the differences in capability may flatten — much like what happened in the smartphone market.

And the more features are added, the more users who can't fully utilize them. Just as most people don't use everything their smartphone can do, the voice of "I don't need that feature" will grow louder.

Because what's necessary varies completely from person to person.

There's another way to look at this.

Like all instruments becoming a single all-purpose keyboard, the deep compatibility with specific thinking types may be lost.

The current natural division of roles is, in effect, functioning as an adaptation to different cognitive layers.

If these differences fade, the boundaries between each AI's role will blur.

Integration is convenient.

But at the same time — the differences between AIs gave rise to cognitive fit, which created a natural division of roles.

There is a possibility that integration dismantles that entire structure.

This is a hypothesis. But as an observation, it's interesting.

■ Still Unknown — But Fascinating

This is not a conclusion.

It is simply a record of observation — a structure that emerged while using multiple AIs in different roles.

If you've felt a similar kind of cognitive fit with a particular AI, or if your observations look completely different, feel free to reach out in the comments or via DM.
